Password to enter: *KRYPTONISGREAT*

Challenge: Within .

```
grep 'password ' bookmarks.html
```

Links & resources

1. When scripting, it is often useful to have a temporary directory where files can be created & modified without the risk of littering such files about the filesystem. So a temporary directory (often in /tmp/) is useful, **mktemp** does this:

move to the new temporary directory

```
cd $(mktemp -d)
```

store the new temporary directory path

```
tmp_dir=$(mktemp -d)
```

2. Git is has many fantastic functionalities, here are some key ones:

compare working tree with committed version

```
git diff <filename>
```

reset working tree file to the committed version

```
git checkout -- <filename>
```

```
git restore <filename>
```

Note: These two methods are destructive, and discard any changes, **git stash** may be more suitable, as it backs up the working tree/changes
